TITLE: The influence of alloying elements on the content and mobility of hydrogen in steel. (Vliyaniye legiruyushchikh elementov na soderzhaniye i podvizhnost' vodoroda v stali).

PERIODICAL: "Stal'" (Steel), 1957, No.6, pp.507-511 (USSR).

ABSTRACT: The results of a study of the content and mobility of hydrogen in binary and ternary iron alloys are described. Alloys, prepared in a high frequency furnace, of the following systems were studied: Fe-C; Fe-Si-C (with 0.12-0.14% of Mn); Fe-Mn-C (with 0.1% of Si); Fe-Zr-C and Fe-Ti-C (with 0.1% Si and 0.1% Mn). The percentage composition of the alloys and their initial hydrogen content are given. The alloys were tested in a forged and cast hardened state. The form of ingots is shown in Fig.1. The determination of hydrogen was carried out by the vacuo-melting method. Experimental results are given in the form of graphs. On the basis of the results obtained it is concluded that alloying elements have a substantial influence on the content and mobility of hydrogen in steel. The content of hydrogen in steel under the same smelting conditions depends on the nature and quantity of alloying elements. According to their influence alloying elements can be

Card 1/2

The influence of alloying elements on the content and mobility of hydrogen in steel. (Cont.) 133-6-8/33

divided on "hydrogen retaining", i.e., increasing hydrogen content in metal (Ti, Zr, C and Mn) and those which have no substantial influence on hydrogen content in metal (Si). The mobility of hydrogen in steel decreases on alloying with every one of the elements investigated, the most effective being hydrogen retaining elements. Plastic deformation and heating for this purpose lead to a substantial decrease of the amount of hydrogen in steels not containing hydrogen retaining elements, and to an insignificant one - in the presence of these elements. The amount of hydrogen evolved at low temperatures (calculated on 100 g of metal) depends on the weight of the metal sample, the smaller the sample, the higher the amount of the evolved hydrogen. There are 6 figures and 9 references, including 5 Slavic.

TITLE: Methods of Determining Hydrogen Depending on the Chemical Composition and Structure of Steel (Metody opredeleniya vodoroda v zavisimosti ot khimicheskogo sostava i struktury stali)

PERIODICAL: Zavodskaya Laboratoriya, 1959, Vol 25, Nr 4, pp 396-398 (USSR)

ABSTRACT: The most used methods for the hydrogen determination in metals employ a heating or melting of the metal in the vacuum. To determine the application possibilities of these methods for the determination of hydrogen in steels cast samples were examined in the present case after quenching in water. The total content of H_2 in the samples was determined after the vacuum melting (VM); the content of hydrogen was then examined by heating in the vacuum (HV), and the kinetics of the hydrogen precipitation was examined for a storing of samples) under mercury at room temperature. The following statements were made: In steels with Ti, V, and Mn with a content of more than 0.5% C, a reduced hydrogen content was ascertained by the HV method (represented graphically in figures a and b) which also applies to carbon-

Card 1/2

507/32-25-4-3/71

Methods of Determining Hydrogen Depending on the Chemical Composition and Structure of Steel

iceous (more than 0.5% c) steels (Fig v) so that these types of steel can only be analyzed by the VM method. Steels containing Nb and Ni (with any content of C) as well as aluminum- and chrome-containing steels (with low content of C) give good results in the hydrogen analysis by the HV method. In alloys with martensite structure, the martensite disintegrates at the temperatures of HV and the formation of a ferrite and carbide phase can take place; this increases the mobility of the hydrogen, and results in better precipitation. For alloys with "movable" hydrogen a storing of samples under mercury is therefore recommended unless the hydrogen analysis is done immediately after the preparation of the samples. There are 4 figures and 6 references, 5 of which are Soviet.

TITLE: Determination of diffusion coefficients of hydrogen in steel at various alloying additions at indoor temperature

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 4, 1961, 4, abstract 4131
("Sb. tr. Tsentr. n.-i. in-t chernoy metallurgii," no. 19, 110 - 116)

TEXT: The diffusion coefficients D of hydrogen in the investigated steels were calculated by experimental data (RZhM, no. 11, 1957, 21133). The boundary-value problem of the theory of diffusion has been solved, where D is found for H diffusion from a sample having the form of a cylinder of 21 height and R radius at a given initial concentration and with a mass exchange on butts and side surface satisfying the boundary conditions of 3rd kind. The solution of the problem $\frac{\partial C}{\partial t} = D [\frac{\partial^2 C}{\partial r^2} + (1/r) \frac{\partial C}{\partial r} + \frac{\partial^2 C}{\partial z^2}]$ is sought for in the form $C(r, z, t)/C_0 = [C'(r, t)/C_0] (C''(z, t)/C_0)$, where $C'(r, t)$ and $C''(z, t)$ are the concentrations in the same point of an unlimited cylinder and unlimited plate by the intersection of which a cylinder of finite dimensions is formed. In the obtained

AUTHOR: Klyachko, Yu. A.; Imanova, T. A.; Chistyakova, I. S. M.TITLE: Gas determination in sheet molybdenumSOURCE: Zavodskaya laboratoriya, v. 29, no. 8, 1963, 923-924

TOPIC TAGS: molybdenum, sheet molybdenum, gas determination, oxygen, hydrogen, nitrogen, carbon monoxide, vacuum-melting method, hydrocarbon

ABSTRACT: Because poorly reproducible results are encountered in gas determination in sheet molybdenum 2-3 mm thick, an analytical method has been developed for determining oxygen, hydrogen, nitrogen, and carbon monoxide in such molybdenum by the vacuum-melting method. About 30% iron or nickel is alloyed with the molybdenum sample to lower its melting point to 1650°C. To drive off moisture and adsorbed gases, the sample is preheated at 200-250°C for 15-20 min in a special quartz extension of the vacuum furnace. Without contact with the air, the sample is then immediately analyzed at 1700°C by the vacuum-melting method. The preheating at 250°C prevents hydrocarbon formation by the reaction of water vapor with molybdenum carbide and thus improves the reproducibility of results.

TITLE: Determination of the oxygen, hydrogen, and nitrogen contents in tungsten, niobium, and tantalum

SOURCE: Zavodskaya laboratoriya, v. 29, no. 12, 1963, 1425-1427

TOPIC TAGS: tungsten, niobium, tantalum, oxygen determination, vacuum melting, tantalum carbides, tungsten carbides, niobium carbides, nitrogen determination, hydrogen determination, vacuum fusion method

ABSTRACT: Because the conventional vacuum-fusion method with iron fluxing bath for determining oxygen, hydrogen, and nitrogen in metals is not reliable in the case of tungsten, niobium, tantalum, and their carbides, a new procedure, applicable to these metals, was developed. For tungsten, tantalum, and niobium, the iron fluxing bath is replaced by cobalt, nickel, and nickel, respectively. The use of cobalt and nickel as fluxing metals provides higher fluidity of the melts and quantitative evolution of the gases to be determined. The concentration of the analyzed metals in the melts should not exceed 30%. The

Card 1/2

ACCESSION NR: AP4005078

fluxing baths are degassed at 1900C for 10-15 min, and liberation of the gases is carried out at 1750-1800C. With the nickel fluxing bath, oxygen is determined with a relative error of 2% in niobium and 5% in tantalum. The procedure is also applicable for the determination of the gases in the carbides of these metals. Orig. art. has: 4 tables.

73. The significance of the humidity of the air in textile strength tests, by F. Izmay, "Magyar Textiltechnika" - Hungarian Textiles Vol. III, No. 3, pp. 87-89, March, 1950.)

The Hungarian standard prescribes for strength tests of textiles stipulate a 65 per cent relative humidity of the air and 20°C temperature. The article provides a thorough explanation and definition of the notion of relative humidity of the air. In the event that these requirements are not complied with the test results must be rectified by the application of correction values. The method of calculation is shown in tables. The rate of hygroscopicity of the more important textile raw materials in relation to their dry weight is indicated in a table. Another table shows in percentage the wet strength brought into correlation to the dry strength.

✓ 4691. Theory and methods for testing the abrasion of cloth and the results of tests carried out by the Textile Research Institute on the abrading apparatus. E. Lepak and E. Brugha. Magyar Testkut, 11-34, No. 2, '61-4, No. 3, 87-91; Hungarian Text, abr., 1964, 6, No. 4, 120-7 abr. 82. J. Text. Inst., 1958, 48, 531A. Cloth abrasion tests conducted over a period of several years proved that the most suitable method consists in abrading cloth with cloth in a manner which ensures identical abrasion stress for both strips to be tested. On the abrading apparatus of the (Hungarian) Textile Research Institute, the stretching of cloth on the cylinder and the pressure of the cylinders against each other are adjustable; the alternating rotation is 100/100 and a fan is used as an inducer for the cloth and lumen formed during abrasion. 664427

✓ 110. Influence of various pretreatments upon the swelling of hemp fibres. E. Léonay, J. K. 3114; *Mémoires de la Société de l'Industrie Textile*, 1955, No. 7, pp. 217-230, 6 figures, 3 tables.

Mallin

2

The authors studied the changes in the swelling ability of hemp fibres after the following treatments: (1) Boiling with soap and soda ash, (2) Kier boiling with caustic soda, (3) Noncorrosive bleaching with sodium chlorite, (4) Kier boiling and bleaching with sodium chlorite, (5) acid hydrolysis, (6) impregnation with basic copper carbonate against microbial degradation. In each case an increase in the swelling ability could be observed which indicates that the swelling of the bast fibres is not caused primarily by the pectins. With the gradual removal of the pectin substances the intercapillary voids within the fibres increase, the structure of the fibres become looser thereby increasing the accessibility. In case of untreated bast fibres it can be assumed that the capillaries of the fibres are closed or at least narrowed by the swelling pectins thereby preventing further water absorption after the initial swelling. The X-ray photographs taken in a dry state also indicate loosened fiber structures. This explains the fact that although the greater part of the strongly swelling pectins has been removed during the treatments, the remaining bast cellulose swells to a far greater extent than the initial bast fibre containing pectins in large quantities. The degree of swelling was measured by a new microscopic method.

✓ FIG. Test methods for tarpaulins. P. Kramay. *Magazin Textiltechnik* 1955, No. 9, pp. 328-330, 3 figs., 1 tab.

Maze

Methods of testing the water permeability of tarpaulins are not satisfactory because: (a) The surface of the tarpaulin and the impregnating agent with which it is treated does not remain smooth, the tarpaulin creases and if not properly impregnated the impregnating substance breaks up and falls out. (b) In practice a water column higher than 200 mm never occurs since the tarpaulin never sags more than 200 mm. (c) A few drops of water appearing on the dry side can not determine the effectiveness of impregnation. More recently tests have been carried out by clamping a 25 x 25 cm specimen rolled into a tube-like shape on a creasing apparatus, twisting it at first in one sense and then in the other through 2×360 degrees. This is repeated ten times. Subsequently the specimen is turned through 90 degrees and the whole procedure repeated. The water pressure obtained by a Mariotte's flask remains constant in spite of decreasing water level. The Mariotte's flask is lifted by a motor at a speed of 100 mm per min., stopping when a level of 200 mm has been reached. Water volumes permeating the tarpaulin in 10, 20, 30, etc. minutes are recorded. For 20 minutes permeability is high, thereafter it decreases due to the swelling of the yarns.

ABSTRACT

When studying the influence exercised by gravity on the polarization of plants the authors cultivated them in an upside-down position. They were able to observe interesting changes of morphological polarity. Their aim was to explain the type of metabolism in the branches of the hanging forms, i.e. of woody plants with a naturally disturbed polarity of the aerial parts. For this purpose the concentrations of the substances mentioned above were determined at three different levels, i.e. at the base, in the middle and at the top of branches. This was done in both the hanging and the normal forms of the following plant species: ash-tree, willow, Sophora japonica, Forsythia and Caragana. When analyzing the chlorophyll concentrations found (tabl.1) it can be seen that they rise towards the top of the branches. The chlorophyll content is lower in young leaves. In the hanging varieties of plants the chlorophyll content is lower than in normal ones. Furthermore a considerable difference was observed between different plant species. Quite similar conditions were in the case of the ascorbic acid

Calculation of the Magnetic Field due to Plane Circuits

$$= \frac{1}{r} \sum_{n=0}^{\infty} \left(\frac{r_0}{r}\right)^n P_n(\cos\gamma), \quad r_0 < r; \quad (2)$$
$$\frac{1}{r} = (r^2 + r_0^2 - 2rr_0 \cos\gamma)^{-\frac{1}{2}}$$

$$= \frac{1}{r_0} \sum_{n=0}^{\infty} \left(\frac{r}{r_0}\right)^n P_n(\cos\gamma), \quad r_0 > r; \quad (2)$$
$$n = 0, 1, 2, 3, \dots$$

where $\cos\gamma = \cos\theta \cos\theta_0 + \sin\theta \sin\theta_0 \cos(\alpha - \alpha_0)$, (3)

$$P_n(\cos\gamma) = \sum_{m=0}^n \frac{(n-m)!}{(n+m)!} \delta_m^m P_n^m(\cos\theta_0) P_n^m(\cos\theta) \cos m(\alpha - \alpha_0). \quad (4)$$
$$(4)$$

In these expressions, P_n is the Legendre polynomial, P_n^m is the associated Legendre function and $\delta_m^m = 2$ when $m = 0$ and $\delta_m^m = 1$ when $m \neq 0$. Fig.1 shows the meaning of the other symbols employed.

Title : Discussion on methods of investigating the dispersibility of electrolytes

Periodical : Zhur. fiz. khim. 28/1, 179-185, Jan 1954

Abstract : The advantages and disadvantages of numerous methods introduced for the study of electrolyte dispersibility during cathodic deposition of metals are listed. A majority of examples mentioned in this report were found to be of an empirical nature. The quantitative characteristic of electrolyte dispersibility was found to be closely connected with the working method and depends upon the conditions of the experiment. The formulas presented place electrolyte dispersibility in close dependence upon the polarization of the electrode, electrical conductivity of the solution and many other factors. Twenty-eight references : 7-USA ; 2-German; 1-English; 18-USSR (1876-1953).

Title : Dispersibility of complex Cu-electrolytes containing ethanolamines

Periodical : Zhur. fiz. khim. 28/2, 229-235, Feb 1954

Abstract : The effect of concentration and other factors on the dispersibility and distribution of Cu on a Cu-cathode, in complex ethanolamine containing electrolytes, was investigated. The introduction into the electrolyte of a complex forming agent - monoethanolamine and triethanolamine - was seen to increase the dispersibility and better distribution of the metal. Increased temperature decreases the dispersibility of the electrolyte and impairs the distribution of the metal. The effect of the electrode potential on the dispersibility and distribution of the metal is discussed and a direct dependence and parallelism between the dispersibility of the electrolyte and the magnitude of the activation energy was established. Six references: 5-USSR and 1-USA (1923-1952). Diagrams; graphs.

Title : Dispersibility of complex Cu electrolytes containing sodium pyrophosphate

Periodical : Zhur. fiz. khim. 28/2, 236-239, Feb 1954

Abstract : The dispersibility and distribution of a metal on the surface of an angular cathode, during the deposition of Cu in the presence of pyrophosphate solutions, was investigated. It was established that temperature changes in the case of electrolytes having pyrophosphate additions do not affect the dispersibility and metal distribution on an angular cathode. The magnitude of the electrode potential had a definite opposite effect on the dispersibility and metal distribution. The effect of the concentration, of the introduced complex forming agent ($Na_4P_2O_7$), is explained. An entirely different mechanism of the cathodic process was observed during the Cu-ion discharge from the pyrophosphate electrolytes. Three USSR references (1949-1954). Graphs.

Title : Theory of dispersibility of complex cupric electrolytes

Periodical : Zhur. fiz. khim. 28/9, 1529-1538, Sep 1954

Abstract : Experiments with complex cupric electrolytes showed that the nature of its dispersibility is determined by the mechanism of the cathodic process and type of polarization. The two possible mechanisms of the cathodic process, during cathode separation of metals from solutions of complex compounds, are explained. A definite relation between dispersibility and temperature, cathode potential and concentration of the complex forming agent was established. A theoretical approach toward selection of conditions most favorable for the obtainment of best dispersibility for electrolytes is presented. Sixteen references: 13-USSR; 2-USA and 1-German (1910-1954). (Graphs.

TITLE: Cathodic Polarization in the Deposition of Silver From Cyanide and Iodide Solutions (Katodnaya polyarizatsiya pri osazhdenii serebra iz tsianistykh i yodidnykh rastvorov)

PERIODICAL: Nauchn. dokl. vyssh. shkoly. Khimiya i khim. tekhnol., 1958, Nr 1, pp 23-27

ABSTRACT: To determine the type of cathodic polarization and to study the mechanism of the cathodic process in cyanide and iodide silver-plating electrolytes the method of the effect of temperature on the rate of electrolysis together with the investigation of the variation of viscosity and electrical conductivity with temperature was employed. The conclusion on the complex mechanism of the electrode process is drawn on the basis of the analysis of the relationship of activation energy with the polarization potential (the activation energy was calculated from the slope of the linear relationships $\log I$ to $1/T$. Depending on the conditions of the electrolysis both concentrational and chemical polarization is possible. The investigations of

TITLE: Cathodic Polarization During the Deposition of Copper From Cyanide and Sulfocyanate Solutions (Katodnaya polyarizatsiya pri osazhdenii medi iz tsianistykh i rodanistykh rastvorov)

PERIODICAL: Nauchn. dokl. vyssh. shkoly. Khimiya i khim. tekhnol., 1958, Nr 1, pp 28-31

ABSTRACT: The type of cathode polarization in cyanide and sulfocyanate copper-plating electrolytes was studied by the method of the effect of temperature on the rate of electrolysis and the method of rapid plotting of polarization curves, together with investigation of the variation in viscosity and electrical conductivity in relation to temperature. With a constant potential difference, the relationship $\log I$ to $1/T$ is expressed by straight lines the slope of which depends on the nature of the complex ion and on the polarization potential of the electrode. The slope of the straight lines yields the values of the activation energy of the electrode process A_{ac} and establishes the effect of the polarization potential on the value of A_{ac} .

Card 1/2

SOV/137-58-9-1956b

Cathodic Polarization During the Deposition of Copper (cont.)

The assumption is exposed that the segments of the A_{ae} - ΔE curves where a strong relationship between A_{ae} and the polarization is observed indicate a chemical polarization in the given segment; the segments of the curves in which A_{ae} does not vary with the polarization potential and which are located within the 3500-4000 cal range indicate a concentrational polarization. The computation of the activation energy of the viscous flow and of the electrical conductivity produced values close to A_{ae} , verifying the reliability of the data. In the solutions investigated, chemical polarization is the fundamental one, but, depending on the conditions of the electrolysis, various mechanisms of the process of electrolysis with a gradual transition from one to the other are possible.

SOV/153-58-2-26/26

TITLE:

Action of Sulfuric Acid on the Process of Electrolytic
Copper Separation (Vliyaniye sernoy kisloty na protsess
elektroosazhdeleniya medi)

PERIODICAL:

Izvestiya vysshikh uchebnykh zavedeniy. Khimiya i khimicheskaya
tekhnologiya, 1958, Nr 2, pp 118-126 (ESSR)

ABSTRACT:

The investigation of the mechanism of the cathodic process under review in the presence of sulfuric acid is of both theoretical and practical importance, in particular for electrolytic refining and the galvanoplastics. Le-Blanc (Ref 1) explains the thus arising hyper-polarization by the retarded ion dehydration. The opinions, however, are rather contradictory (Refs 2-5). This may be explained by the complicated mode of the process itself as well as by the methods of investigation which were not quite suitable. It is further important to elucidate the influence exerted by the H_2SO_4 concentration and other factors upon the mechanism of the cathodic process and upon the type of polarization. In order to clarify the latter

Card 1/4

Action of Sulfuric Acid on the Process of
Electrolytic Copper Separation

SCI/153-56-1-20,50

type and the mechanism, the author investigated the variation of viscosity and electric conductivity with the varying temperature. This was carried out by the method of the temperature action exercised upon the electrolysis rate (Ref 6) and by the method of the rapid plotting of polarization curves (Ref 7). The test methods and the apparatus were described by the author in an earlier paper (Ref 8). a) The action of temperature exercised upon the cathodic polarization in the copper separation from CuSO_4 -solutions with additions of Fe_2SO_4 is shown in figure 1. The sharp decrease of polarization with increasing temperature is here the most characteristic one. Yet, the number of active molecules within the electrolyte and the diffusion rate of complex metal ions is increased here. The polarization curves for 0,1 and 0,01 M- CuSO_4 -solutions (Fig 2) and the temperature coefficient are discussed. The latter varies with the concentration of copper sulfate, the current density and temperature. Figure 4 gives the A_e -quantities calculated from the angle of inclination, i. e. the effective activation energy of the electrolytic process. b) It was found that the A_e -quantities were the highest with low polarization potentials in all electrolytes investigated.

Card 2/4

Action of Sulfuric Acid on the Process of
Electrolytic Copper Separation

SO7/153-58-2-20/30

If for each electrolyte a certain quantity of the polarization potential is reached, the A_e -quantities fall down to 8000 cal/mol. A further increase of polarization does scarcely influence the A_e -quantity. Table 1 presents the quantities of the coefficient α which shows the effect exercised by the near electrode field upon the decomposition of the complex ions. It can be seen from figure 5 that the cathodic polarization scarcely depends on its rate of measurement. This indicates that the cathodic polarization for the corresponding electrolyte has, more or less, the character of chemical polarization.

c) The action of the H_2SO_4 concentration exercised upon the velocity of the electrodic process permits the investigation of the nature of the inhibitory process of the electrochemical reaction and the determination of the mode of action of these or those additions exercised upon the electrodic process. Figure 6 shows the influence exercised by the H_2SO_4 concentration upon the cathodic polarization in 1, 0,1 and 0,01 M-solutions of $CuSO_4$. It was found that H_2SO_4 usually inhibits the cathodic process to a considerable extent,

Card 3/4

SOV/155-58-2-20/30

Action of Sulfuric Acid on the Process of
Electrolytic Copper Separation

which is accompanied by increased polarization. Thus, the mechanism of the electrodic process was clarified. According to the conditions of electrolysis different mechanisms and transitions between them are possible. The mechanism of the cathodic process depends both on the concentration of the basic electrolyte and on that of H_2SO_4 . Professor S. V. Gorbachev gave helpful advice. There are 7 figures, 2 tables, and 14 references, 9 of which are Soviet.

TITLE:

Investigation of the Influence Exerted by Surface-Active Compounds Upon the Kinetics of Copper Electrolytically Deposition From Sulfate Solutions (Issledovaniye vliyaniya povrchnostno-aktivnykh sredstv na kinetiku elektroosazhdeniya molaia v svereskialykh rastvorov)

PERIODICAL:

Izvestiya vuzov ushebnykh zavedeniy. Khimika i khimicheskaya tekhnika, 1958, Nr 2, pp 127-134 (USSR)

ABSTRACT:

Some colloids and surface-active compounds inhibit, even in small amounts, the ionic discharge and increase considerably the cathodic polarization. According to nature and concentration galvanic precipitate of different form can be obtained (Refs 1-8). In spite of ample practical application both the nature of the mentioned inhibition and the type of the cathodic polarization are not yet clarified in many regards. The author presents a survey of the publications (Refs 9-15). In the present paper the author tried to clarify the nature of the inhibitory influence of additions of thiourea and of a mixture of the latter with black molasses. Furthermore, the quantities

Card 1/3

SOV/153-18-2-2151
Investigation of the Influence Exerted by Surface-Active Compounds Upon the
Kinetics of Copper Electrolytically Separated From Sulfate Solutions

molasses, respectively, (Fig 1, Curve 7) the curves are quite different; the variation of A in dependence on the polarization potential is quite a different one than that effected with the chemical, concentration- or phase polarization (Ref. 36). In these cases, A is considerably higher than for the basic electrolyte without additions. The diffusion is still forming the inhibitory process. A further increase of the polarization potential reduces the A -quantities down to those being characteristic of the basic electrolyte with the corresponding polarization potential. This means that the most retarded stage of the electrode process apparently passes at the surface of the electrode. The occurrence of a new particular kind of polarization may be explained apparently by the inhibition produced by a dense adsorption layer at the electrode surface consisting of molecules of the added surface-active compound. The author intends to call this type of polarization "adsorption polarization". The increase of activation energy may be explained by an increasing viscosity due to the formation of a viscous film. The influence exercised by the concentration of a

TITLE: Several Problems of Kinetics in the Cathodic Processes of
Electrolytic Deposition of Metals (Nekotoryye voprosy kinetiki
katodnykh protsessov pri elektroosazhdennii metallov)

PERIODICAL: Nauchnyye doklady vysshykh koly, Khimiya i khimicheskaya
tekhnologiya, 1958, Nr 2, pp. 240 - 244 (USSR)

ABSTRACT: As is known, metal ions pass through several stages in
electrolysis before they become a part of the crystal lattice
of the deposition. Thus the velocity of the process is limited
by the slowest stage. In spite of numerous investigations the
mechanism of the discharge of cations in solutions of simple
salts is still not clear (Ref 1). This mechanism is even less
clear for solutions of complex ions. This complicates the control
of galvanic processes and the choice of optimum conditions for
electrolysis. It was early discovered that with the clarification
of the type of cathodic polarization and with the study of the
mechanism of the electrolytic process the dependence of the
current upon the temperature can be evaluated. In regard to the
problem of this paper the author was interested in studying the

Card 1/4

Several Problems of Kinetics in the Cathodic
Processes of Electrolytic Deposition of Metals

SOV/156-58-2-1a/48

the indicated solutions at different temperatures and the calculated energies of activation. These data indicate that for solutions 2,3,6,7, and 9 the increase in temperature apparently influences the product $\eta \cdot k$. This indicates that the ion structure is markedly changed with change in temperature. This factor must have some influence upon the quality of the depositions involved. Therefore one should prevent increases of temperature in galvanic cells whose electrolyte structure is thus impaired by change of temperature. On the other hand, however, this is allowed for the following electrolytes: cyanogen-containing copper-plating, silver-plating, cadmium-plating, and tin-plating electrolytes. An increase in temperature is even desirable here, since a greater current density is produced and the productivity increases (Refs 12 - 14). Professor S.V.Gorbachev gave valuable suggestions and took part in the discussion over the work. There are 3 figures, 1 table, and 15 references, 13 of which are Soviet.

Concerning the Relationship Between the Effective Energy SOV, 156-58-2-11/48 of Activation of Electrolytic Processes, the Stability of Complex Ions, and the Valence of Ions Dissociating From the Complex

energy for the dissociation of the complex ions. The degree of dissociation can be calculated according to an equation. The author was interested in investigating the relationship between the effective energy of activation of the electrolytic process, the instability constant of each complex ion, and other factors. As is evident from figure 1, the energy of activation is greatest when the polarization potential is lowest. The increase in polarization considerably decreases the energy of activation. Figure 2 shows that for both univalent and divalent ions the quantity K_n decreases when the quantity A_0 decreases (A is the energy of activation at $\Delta E=0$). From the polarization curves given in figure 3 it follows that for the electrolytes II. and III., and I. and IV., which contain complex ions of like valence but different instability constants, the polarization curves differ (Electrolyte I. = Zn, NaCN, NaON; II. CuSO₄, triethanolamine; III. CuSO₄, Na₂C₂O₄; IV. CuCN, NaCN, Na₂CO₃).

TITLE:

Kinetics of the Electroseparation of Zinc and Cadmium From
Solutions of Simple and Complex Salts

PERIODICAL:

Izvestiya vysshikh uchebnykh zavedeniy. Khimiya i khimicheskaya
tekhnologiya, 1959, Vol 2, Nr 4, pp 562 - 567 (USSR)

ABSTRACT:

The problem mentioned in the title (also with various additions to the electrolyte) is of practical as well as theoretical interest. Despite several investigations in this field, most of the respective problems as well as those of cathodic polarization are unsolved or questionable (Refs 1-9). The paper under discussion aims at obtaining additional data concerning the nature of cathodic polarization in the process mentioned in the title as well as explaining the effect of the nature of the electrolyte and other factors on the mechanism of the cathodic process. For this purpose, the variation of viscosity and electric conductivity with temperature was investigated in addition to the method of temperature effect on the electrolysis rate (Ref 10) and the method of a rapid plotting of the polarization curves according to A. T. Vagramyan (Ref 11). The

Card 1/4

Kinetics of the Electroseparation of Zinc and Cadmium
From Solutions of Simple and Complex Salts

SO7/153-2-4-18/32

effect of the field near the electrode on the discharge mentioned. According to the nature of the suppressing process in the complex cyanogen electrolytes, a variable mechanism of the cathodic process is observed which is brought about by polarization caused chemically or by the concentration. With regard to the acid zinc- and cadmium electrolyte it was found that the activation energy does not depend on the polarization potential. The diffusion rate of the ions to the electrode suppresses the electrochemical process. Thus, concentration polarization occurs. Moreover, the following Soviet names were mentioned in the paper: Yesin, O. A., Titov, P. S., Boldanova, N. N., Gorbachev, S. V., Starostenko, Ye. P., Rcyter, V. A., Yuza, V. A., Poluyan, Ye. S., Zgaryshev, N. A. There are 6 figures, 2 tables, and 17 references, 15 of which are Soviet.

viscosity and electric conductivity with temperature. The methods and the apparatus had been described earlier (Refs 12,13). There is a linear dependence of all electrolytes investigated in the case of a polarization potential ΔE in coordinates

$\lg I - \frac{1}{T}$. The inclination angle of the straight line depends on the nature of the electrolyte and the potential. The values of the effective activation energy computed from this angle are shown in figure 2 and table 1. The linear dependence mentioned is preserved over a wide range of polarization potentials. The author determined the values of coefficient α with various ΔE from the experimental values of the activation energy A . According to the electrolysis conditions (polarization potential and degree of current density), a variable mechanism of the cathodic process of lead separation can be observed. This is caused by chemical or concentration polarization. The results obtained prove that the mechanism mentioned is characterized by concentration polarization in lead separation from stannate solutions. Moreover, the following Soviet names were mentioned

TITLE: Deposition of metallic platings on welded products of titanium and its alloys

SOURCE: Zashchita metallov, v. 1, no. 2, 1965, 238-239

TOPIC TAGS: titanium alloy, titanium, metal deposition, nickel plating, copper plating, electroplating

ABSTRACT: A technique recommended for preparation of high quality copper platings on welded articles of titanium or its alloys is described in detail. It consists of the following steps: 1. mechanical removal of the sinter (only for gas welded samples); 2. degreasing with organic solvents; 3. etching at 70°C for up to 30 min in a solution containing (vol. %): conc. HF-5, conc. H₂SO₄-35, and H₂O-60; 4. copper plating at 20°C for 2 min at a current density of 1-2 A/100 cm² in a solution containing (g/l): CuSO₄·5H₂O-250, conc. H₂SO₄-50, and conc. HF-50, up to complete

Class 8, no. 178258

SOURCE: Izobreteniya, promyshlennyye obrantsy, tovarnyye znaki, no. 2,
1966, 146

TOPIC TAGS: tin alloy, electrodeposition, electrolyte, metal deposition, molybdenum alloy

ABSTRACT: This Author Certificate describes an electrolytic method of depositing a tin-molybdenum alloy. In order to produce a fine-crystalline structure for the alloy, the electrolysis is made from an electrolyte of the following compositions, (in grams per liter): ammonium molybdate, 40-60; sodium stannate, 10-20; sodium pyrophosphate, 40-80; sodium bicarbonate, 10-40; hydrazine sulfate, 1-3. deposition

ABSTRACT: An Author Certificate has been issued for a method of chemical
deposition of nickel-phosphorus alloys from a sulfate solution. To obtain a firm
cohesion of the coating with such metals as lead, tin, magnesium, zinc, cadmium,
and antimony, the process is carried out in a solution of the following composition
(in g/l): 25—35 nickel sulfate, 15—20 sodium hypophosphate, 50—75 diethanola-
mine, and 25—30 ammonium fluoride at temperatures of 85—95°C and pH of 8.5—
9.5. [Translation]

TITLE: Telomerization of dimethyl cyclootetrasiloxane. Communication 5. Reactions with trifunctional compounds.

PERIODICAL: Akademika nauk SSSR. Izvestiya. Otdeleniye khimicheskikh nauk, no. 2, 1963, 282 - 290

TEXT: Reacting hexamethyl cyclootetrasiloxane (I) with organotrichloro silanes at 250°C led to the formation of telomers of the formula $RSi(Cl)_3 - [OSi(CH_3)_2]_nSi$ in which the degree of telomerization depended on the organic radical R. The activity of $RSiCl_3$ decreased in the order $R = CH_3, C_2H_5, CH_2-CH_3, C_6H_5$. When 2 was CH_3 or C_2H_5 , a 1:2 excess of I effected a reduction of the yield in the telomer with $n = 1$, a slight increase of the telomers with $n = 2$ and $n = 3$, and a sharp increase of the higher telomers. This effect was absent, when the reaction with CH_3SiCl_3 was brought about in two stages with separation of 1,1,7-trichloro-hepta-methyl tetracosiloxane. This is attributed to the dependence of the $RSiCl_3$

TITLE: Hydrolytic polycondensation of higher alkyltrichlorosilanes

SOURCE: Zhurnal obshchey khimii, v. 36, no. 2, 1966, 341-345

TOPIC TAGS: organosilicon compound, polycondensation, hydrolysis

ABSTRACT: Reactions of hydrolytic polycondensation of hexyl-, heptyl-, octyl-, and isononyltrichlorosilane were investigated. The hydrolysis was found to differ considerably from that of lower alkyltrichlorosilanes. Even when carried out in an acid medium, the initial products contained a large number of hydroxyl groups. The reaction is represented as follows:

The products were polymeric compounds of relatively low molecular weight. In order to achieve a complete condensation of the hydroxyl groups, compounds (I-IV) were distil-

Card 1/2

led under a high vacuum; this produced low-molecular three-dimensional rings, silsesquioxanes, which are viscous liquids soluble in benzene, toluene, and ether. The IR spectra of the silsesquioxanes showed the presence of an absorption band at 1125 cm^{-1} , which was attributed to the stretching vibration of the Si-O-Si bond. The experimental data indicate that the higher alkyltrichlorosilanes have a much greater tendency toward intramolecular condensation during hydrolytic condensation than lower alkyltrichlorosilanes, in which hydrolytic condensation also readily occurs intermolecularly. The intramolecular character of the process is attributed to pronounced steric hindrance effects due to bulky radicals; this accounts for the formation of ring structures instead of polymers.
